How many molecules are in 1 mole of water

Learning Objectives Define mole and molar mass. Perform calculations to convert between moles and mass of a substance. Perform calculations to convert between mass of a substance and number of particles. It certainly is easy to count bananas or to count elephants (as long as you stay out of their way). However, you would be counting grains of sugar from your sugar canister for a long, long time. Atoms and molecules are extremely small - far, far smaller than grains of sugar. Counting atoms or molecules is not only unwise, it is absolutely impossible. One drop of water contains about (10^{22}) molecules of water. If you counted 10 molecules very second for 50 years without stopping you would have counted only (1.6×10^{10}) molecules. Put another way, at that counting rate, it would take you over 30 trillion years to count the water molecules in one tiny drop. Chemists needed a name that can stand for a very large number of items. Amadeo Avogadro (1776 - 1856), an Italian scientist, provided just such a number. He is responsible for the counting unit of measure called the mole. A mole $(\text{left}(\text{mole} \text{ right}))$ is the amount of a substance that contains (6.02×10^{23}) representative particles of that substance. The mole is the SI unit for amount of a substance. Just like the dozen and the gross, it is a name that stands for a number. There are therefore (6.02×10^{23}) water molecules in a mole of water molecules. There also would be (6.02×10^{23}) bananas in a mole of bananas, if such a huge number of bananas ever existed. Figure $(\text{PageIndex}1)$ Italian scientist Amadeo Avogadro, whose work led to the concept of the mole as a counting unit in chemistry. The number (6.02×10^{23}) is called Avogadro's number, the number of representative particles in a mole. It is an experimentally determined number. A representative particle is the smallest unit in which a substance naturally exists. For the majority of elements, the representative particle is the atom. Iron, carbon, and helium consist of iron atoms, carbon atoms, and helium atoms, respectively. Seven elements exist in nature as diatomic molecules and they are (H_2) , (N_2) , (O_2) , (F_2) , (Cl_2) , (Br_2) , and (I_2) . The representative particle for these elements is the molecule. Likewise, all molecular compounds such as (H_2O) and (CO_2) exist as molecules and so the molecule is their representative particle. For ionic compounds such as (NaCl) and $(\text{Ca}(\text{NO}_3)_2)$, the representative particle is the formula unit. A mole of any substance contains Avogadro's number $(\text{left}(6.02 \times 10^{23} \text{ right}))$ of representative particles. Figure $(\text{PageIndex}2)$ The animal mole is very different than the counting unit of the mole. Chemists nonetheless have adopted the mole as their unofficial mascot. National Mole Day is a celebration of chemistry that occurs on October 23 $(10/23)$ of each year. We can use Avogadro's number as a conversion factor, or ratio, in dimensional analysis problems. If we are given the number of atoms of an element X, we can convert it into moles by using the relationship $(\text{mole} = \frac{\text{number of atoms}}{6.02 \times 10^{23}})$. Example $(\text{PageIndex}1)$: Moles of Carbon The element carbon exists in two primary forms: graphite and diamond. How many moles of carbon atoms is (4.72×10^{24}) atoms of carbon? Solution Steps for Problem Solving The element carbon exists in two primary forms: graphite and diamond. How many moles of carbon atoms is (4.72×10^{24}) atoms of carbon? Identify the "given" information and what the problem is asking you to "find." Given: (4.72×10^{24}) C atoms Find: mol C List other known quantities $(1 \text{ mole} = 6.02 \times 10^{23})$ C atoms Prepare a concept map and use the proper conversion factor. Cancel units and calculate. $(\frac{4.72 \times 10^{24} \text{ atoms}}{6.02 \times 10^{23} \text{ atoms/mole}} = 7.84 \text{ moles})$ Think about your result. The given number of carbon atoms was greater than Avogadro's number so the number of moles of (C) atoms is greater than 1 mole. Since Avogadro's number is a measured quantity with three significant figures, the result of the calculation is rounded to three significant figures The molar mass of a substance is defined as the mass in grams of 1 mole of that substance. One mole of isotopically pure carbon-12 has a mass of 12 g. For an element, the molar mass is the mass of 1 mol of atoms of that element; for a covalent molecular compound, it is the mass of 1 mol of molecules of that compound; for an ionic compound, it is the mass of 1 mol of formula units. That is, the molar mass of a substance is the mass (in grams per mole) of 6.02×10^{23} atoms, molecules, or formula units of that substance. In each case, the number of grams in 1 mol is the same as the number of atomic mass units that describe the atomic mass, the molecular mass, or the formula mass, respectively. The molar mass of any substance is its atomic mass, molecular mass, or formula mass in grams per mole. The periodic table lists the atomic mass of carbon as 12.011 amu; the average molar mass of carbon—the mass of 6.022×10^{23} carbon atoms—is therefore 12.011 g/mol. Table $(\text{PageIndex}1)$ Molar Mass of Select Substances Substance (formula) Basic Unit Atomic, Molecular, or Formula Mass (amu) Molar Mass (g/mol) carbon (C) atom 12.011 (atomic mass) 12.011 ethanol (C₂H₅OH) molecule 46.069 (molecular mass) 46.069 calcium phosphate [Ca₃(PO₄)₂] formula unit 310.177 (formula mass) 310.177 The molar mass of any substance is the mass in grams of one mole of representative particles of that substance. The representative particles can be atoms, molecules, or formula units of ionic compounds. This relationship is frequently used in the laboratory. Suppose that for a certain experiment you need 3.00 moles of calcium chloride $(\text{left}(\text{CaCl}_2 \text{ right}))$. Since calcium chloride is a solid, it would be convenient to use a balance to measure the mass that is needed. Dimensional analysis will allow you to calculate the mass of (CaCl_2) that you should measure as shown in Example $(\text{PageIndex}2)$. Example $(\text{PageIndex}2)$: Calcium Chloride Calculate the mass of 3.00 moles of calcium chloride (CaCl₂). Figure $(\text{PageIndex}3)$ Calcium chloride is used as a drying agent and as a road deicer. Solution Steps for Problem Solving Calculate the mass of 3.00 moles of calcium chloride (CaCl₂). Identify the "given" information and what the problem is asking you to "find." Given: 3.00 moles of CaCl₂ Find: g CaCl₂ List other known quantities 1 mol CaCl₂ = 110.98 g CaCl₂ Prepare a concept map and use the proper conversion factor. Cancel units and calculate. $(3.00 \text{ moles} \times \frac{110.98 \text{ g}}{1 \text{ mole}} = 333 \text{ g})$ Think about your result. Example $(\text{PageIndex}3)$: Water How many moles are present in 108 grams of water? Solution Steps for Problem Solving How many moles are present in 108 grams of water? Identify the "given" information and what the problem is asking you to "find." Given: 108 g H₂O Find: mol H₂O List other known quantities $(1 \text{ mole} = 18.02 \text{ g})$ H₂O Prepare a concept map and use the proper conversion factor. Cancel units and calculate. $(\frac{108 \text{ g}}{18.02 \text{ g/mole}} = 6.00 \text{ moles})$ Think about your result. Exercise $(\text{PageIndex}1)$: Nitrogen Gas What is the mass of (7.50 mol) of Nitrogen gas (N_2) ? Answer: 210 g In "Conversions Between Moles and Mass", you learned how to convert back and forth between moles and the number of representative particles. Now you have seen how to convert back and forth between moles and mass of a substance in grams. We can combine the two types of problems into one. Mass and number of particles are both related to moles. To convert from mass to number of particles or vice-versa, it will first require a conversion to moles as shown in Figure $(\text{PageIndex}1)$ and Example $(\text{PageIndex}4)$. Figure $(\text{PageIndex}4)$ Conversion from number of particles to mass or from mass to number of particles requires two steps. Example $(\text{PageIndex}4)$: Chlorine How many molecules is (20.0 mol) of chlorine gas, (Cl_2) ? Solution Steps for Problem Solving How many molecules is (20.0 mol) of chlorine gas, (Cl_2) ? Identify the "given" information and what the problem is asking you to "find." Given: 20.0 mol Cl₂ Find: # Cl₂ molecules List other known quantities 1 mol Cl₂ = 70.90 g Cl₂, 1 mol Cl₂ = 6.022×10^{23} Cl₂ molecules Prepare a concept map and use the proper conversion factor. Cancel units and calculate. $(20.0 \text{ mol} \times \frac{6.022 \times 10^{23} \text{ molecules}}{1 \text{ mol}} = 1.20 \times 10^{25} \text{ molecules})$ Think about your result. Since the given mass is less than half of the molar mass of chlorine, the resulting number of molecules is less than half of Avogadro's number. Exercise $(\text{PageIndex}2)$: Calcium Chloride How many formula units are in 25.0 g of CaCl₂? Answer: 1.36×10^{23} CaCl₂ formula units how many molecules are present in 1 mole of water. how many water molecules are there in 1 mole of h₂o. how many molecules are there in 1 mole of water. how many molecules of water make up 1 mole
